

Pairwise component interaction matrix

Cell = interaction effect (observed degradation - additive prediction) for removing both components; colour = interaction class.

effect < 0 -> the pair degrades LESS than the sum of its parts (shared / saturated plane); effect = 0 -> exactly additive.

10 distinct component pairs (matrix is symmetric; diagonal is undefined).
Components: PE predicate engine, RV runtime revocation, EQ evidence quad, LG runtime ledger, HC hash chain.
A 'Critical Dependency' cell means the two components share a plane, so the second removal costs almost nothing extra -- the damage was already done by the first.
