

Cross-dataset replication: removing the predicate engine raises the undetected-risk rate (URR)

Baseline (full L-DREA) vs remove_PE, on three independent real datasets. Gamma is untouched between datasets.

CAVEAT -- absolute undetected-risk rate (URR)s are NOT comparable across datasets: each has a different attack prevalence and base rate (shown above), so the bar heights of one dataset say nothing about another. The finding that REPLICATES is the RISE: in every dataset, deleting the predicate engine drives the undetected-risk rate (URR) to its ceiling, independent of the base rate it started from.
