

Component dependency DAG (discovered from the live runtime)

Edge A -> B means A CONSUMES B (A depends on B). Columns are topological depth: a component sits to the right of everything it depends on.

node type

- in ablation matrix (5)
- always-on plane (4)

depends on

execution order

PE -> RV -> EQ -> LG -> HC ->
WD -> FT -> CK -> RD

9 components discovered

Discovery method: importlib + inspect probing of live runtime symbols; a component is listed only if its symbol resolves.

The dependency structure explains the interaction matrix: HC depends on LG and EQ, and LG depends on EQ, so removing EQ already destroys the ledger and hash-chain planes -- which is why the EQ+LG and EQ+HC pairs read as Critical Dependency, not as additive damage.
